Builder Pattern — Concepts

- It is a **pattern** that lets **construct** a **complex object** **step by step**. The idea is to **create different representations** of an object using the **same construction code**.
- One typical **problem** is work with a class that has **many attributes** and it is difficult to create an instance of it. It gets worse when there are **many possible representations** of the object.
- Several **attributes** are **optional** and the client has to **specify them** in a specific order. So, this could be a **problem** for both **objects management** and **code maintenance**. Also, **increase memory consumption**.
- The **solution** is to **encapsulate** the object construction and use separate **methods** to add or build the object attributes.

Factory Pattern — Concepts

- It is **pattern** based on a **superclass** and the **subclasses** could alter the **type of objects** to be created.

- One of the **most common** design pattern used, is simple, powerful and flexible. It is used with many other design patterns.

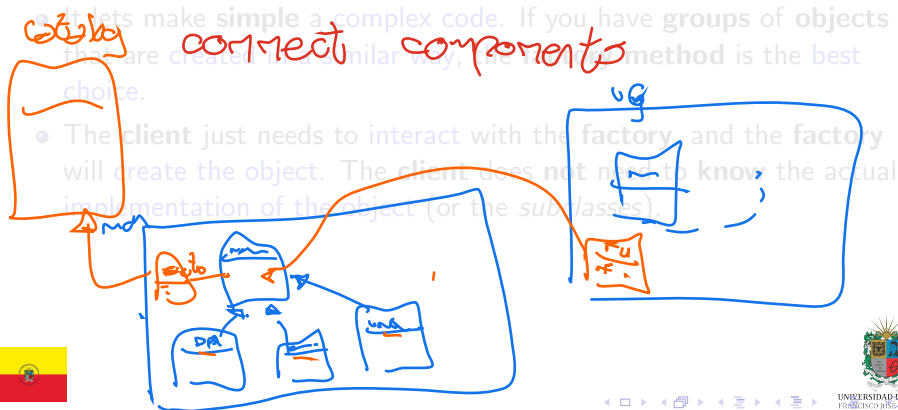

- It lets make **simple** a **complex** code. If you have **groups** of **objects** that are created in a **similar way**, the **factory method** is the **best choice**.

- The **client** just needs to **interact** with the **factory**, and the **factory** will create object. The **client** does **not** need to know the actual **implementation** of the object (or the **subclasses**).

Abstract Factory Pattern — Concepts

Abstract Factory Pattern — Concepts

- This is a **pattern** that lets you **produce families** of **related objects** **without specifying** their **concrete classes**.
- It is a **super factory** that **creates other factories**. It is used when you have a **super class** that can **create subclasses** and the **subclasses** can **create objects**.
- Also this **pattern** allows to keep the **client** code **decoupled** from the **actual objects** in the **system**. Keep **old code** when you need to add **new representations**.
- It is used when you have **many objects** that can be **grouped** in **families**.

Singleton Pattern — Concepts

- In an attempt to **reduce memory consumption**, this **pattern** ensure that a **class** has only **one instance** and provide a **global point of access** to it.

- It is used when you need to **control the number of instances** of a class. **Just one class instance is allowed** across all the application. Also it allows to **apply** the concept of **lazy creation**.

- It is **pretty simple**: just create a class with a method that creates a

new **instance** of the class if **one does not exist**. If an instance **already exists**, it returns a **reference** to that object.

- It **violates** the *Single Responsibility Principle* and the *Open/Closed Principle*. Also, internal instance and **get method** are *static*.

- **Not** a very **good idea** if you are using a **multi-trending application**. It could be issues trying to access a shared single object.

Prototype Pattern — Concepts

- It is based on copy of an existing object. It is used when the type of objects to create is determined by a prototypical instance, which is cloned to produce new objects.
↑ clone
- Remember, clone is not just copy an object, it is create a new object with the same attributes and values of the original object.
↳ libraries
- It solves the problem of copy the private attributes of an object. So, you could create a copy including the hidden logic.
- This pattern delegates the cloning process to the actual objects that are being cloned. This is a good idea because the object knows how to create a copy of itself using an internal method.
- It exists the concept of prototype registry, just to make quick access and save of frequent used objects.
